Biostatistics Week 5

- > Binomial test for proportion
- > Terms in hypothesis tests
 - Significance level, error type I and II, rejection zone, power
- sample size calculation / power analysis
- multiple testing
 - Bonferroni correction (for << 100 tests)
 - False discovery rate, p-value histogram (for >100 tests)

Example: Does new treatment lower the relaps risk?

- Question: Does a new treatment lower the proportion of 35% relapses that is typical for the state-of-the-art treatment.
 Data: we observe 26 relapses among 100 treated patients
- \blacksquare H₀: "nothing changed", proportion of relapses is 35%
- How is the number of relapses among 100 treated patients distributed und H₀?
 - X Number of relapses in 100 treated patients $X \sim Bin(\pi=0.35, n=100)$

How to assess if the observation is consistent with H_0 ?

- Probability to observe x = 26 relapses under 100 treated patients under H_0 :
- $n=100, x=26, \pi=0.35$

[1] 0.01400205

In R:

- What about, if we would have observed x=25 relapses under 100 patients? That would indicate even stronger that H₀ might be wrong.
- **Question (in 2 phrasings)**
 - What is the rejection zone for H_0 ?
 - How large is the probability to observe 26 or less relapses among 100 patients, if H_0 would be correct?

Rejection zone

Look for the maximal range from 0 to k relapses among 100 patients, until the probability of 5% (significance level α) is taken.

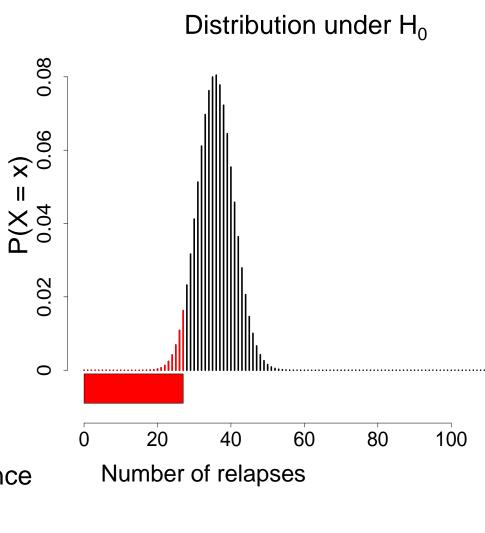

> pbinom(25:27,100,p=0.35) [1] 0.021 0.035 0.055

Probabilities:

0<X≤25 0.021 # below 5% 0<X≤26 0.035 # below 5% 0<X≤27 0.055 # too large

If the observed number x is between 0 and 26, then we have enogh evidence to reject H_0 .

→ Accept H_A

Binomial test in R

Perform a Binomial test R:

```
> binom.test(x=26, n=100, p=0.35,
                                                        Distribution under H<sub>0</sub>
              alternative="less")
        Exact binomial test
data: 26 and 100
number of successes = 26, number of
trials = 100, p-value = 0.03514
alternative hypothesis: true probability
of success is less than 0.35
95 percent confidence interval:
 0.0000000 0.3419918
                                             0.04
sample estimates:
probability of success
                   0.26
# compute the p-valu by hand in R:
> pbinom(26, 100, 0.35)
> 0.0351 # "p-Wert"
                                             0.00
# or calculate p-value via
> sum(dbinom(0:26, 100, 0.35))
> 0.0351
                                                        20
                                                              40
                                                                     60
                                                                           80
                                                                                 100
                                                   Anzahl unzufriedener Mitarbeiter
```

Recall: CI from a 2-sided t-test

$$X_{i} i.d.d. \sim N(\mu, \sigma^{2}), E(X) = \mu_{x}, Var(X) = \sigma_{x}^{2}$$

$$\Rightarrow T = \frac{\overline{X} - \mu_{x}}{s_{x}} \sim t_{df=n-1}$$

$$P(q_{\frac{\alpha}{2}}^{t} \leq \frac{\overline{X} - \mu_{x}}{\sigma_{x}} \leq q_{\frac{1-\alpha}{2}}^{t}) = 1 - \alpha$$

$$P(-\frac{\sigma_{x}}{\sqrt{n}} \cdot q_{\frac{1-\alpha}{2}}^{t} \leq \overline{X} - \mu_{x} \leq \frac{\sigma_{x}}{\sqrt{n}} \cdot q_{\frac{1-\alpha}{2}}^{t}) = 1 - \alpha$$

$$P(\overline{X} - \frac{\sigma_{x}}{\sqrt{n}} \cdot q_{\frac{1-\alpha}{2}}^{t} \leq \mu_{x} \leq \overline{X} + \frac{\sigma_{x}}{\sqrt{n}} \cdot q_{\frac{1-\alpha}{2}}^{t}) = 1 - \alpha$$

One Sample t-test

mean of x

-0.002809773

```
data: sample t = -0.0028096, df = 9999, p-value = 0.9978 alternative hypothesis: true mean is not equal to 0 95 \text{ percent confidence interval:} \\ -1.963121 \quad 1.957501 \qquad 0 \in CI \Longrightarrow don't \text{ reject } H_0 sample estimates:
```

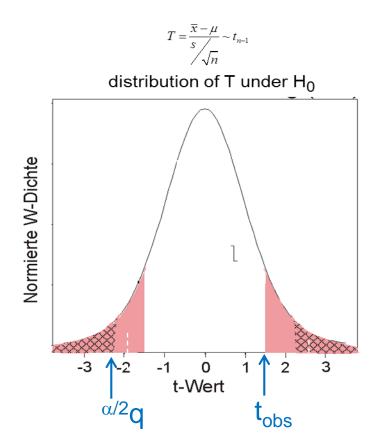

Distribution of T under H₀ CI for μ : if H_0 parameter falls into this region, don't reject H_0

Rejection zone if the H₀ parameter falls into this region, then reject H₀

Recall: Interpretation of the p-value

The p-value corresponds to the probability to get an at least such extreme result as the seen one if we assume that the Null-Hypothesis is valid. (Therefore we reject H_0 if this probability is small)

Graphically: the p-value corresponds to the area in the extreme tails (from the observed t-value outwards) under the density of the test-statistic distribution which is taken for a true H0.

$$p = P(|t| \ge |t_c| \mid H_0 \text{ is true})$$
$$= P(p_{new} \le p \mid H_0 \text{ is true})$$

p-value > 0.1 : no evidence for H_A

p-value < 0.1: weak evidence for H_A

p-value < 0.05: evidence for H_A

p-value < 0.01 : clear evidence for H_A

p-value < 0.001 : strong evidence for H_A

Right-, left- and two-sided Test

z.B.:
$$T = \frac{\overline{x} - \mu_0}{\sqrt[s]{n}} \stackrel{a}{\sim} N(0,1)$$

Right-sided Test:

 H_A : $\mu > \mu_o$

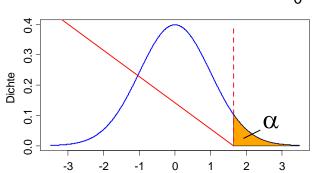

Left-sided Test:

 H_A : $\mu < \mu_o$

Two-sided Test:

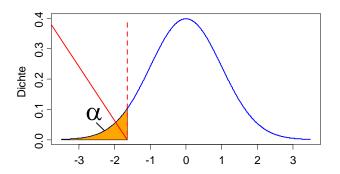

$$H_A$$
: $\mu \neq \mu_o$

Distribution of T under H₀

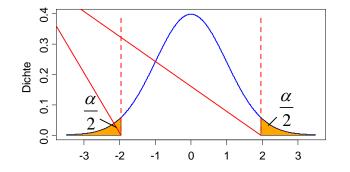

(1-
$$\alpha$$
)-CI for μ

$$\left[\begin{array}{cc} -\infty \;,\; q_{\scriptscriptstyle 1-lpha} \end{array}
ight]$$

$$\left[\begin{array}{c}q_{lpha}\,,\,\infty\end{array}
ight]$$

$$\left[\begin{array}{c}q_{lpha/2}\;,\;q_{(1-lpha/2)}\end{array}
ight]$$

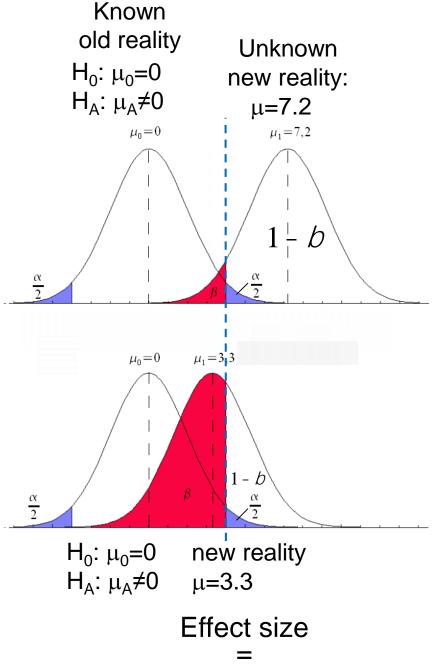

Decision errors revisited

| | negative test accepting H ₀ | positive test rejecting H ₀ | |
|-------------------------|---|---|--|
| H ₀ is true | True Negative (the probability for this correct test decision is (1-α)) | False Positive (the probability for a type-I error is α) | |
| H ₀ is false | False Negative (the probability for a type-II error is β) | True Positive (the probability for this correct test decision | |

 $P(reject \ H_0 \mid H_0 \ true) = \alpha$ probability for type I error

is $(1-\beta)$

 $P(\text{accept } H_0 \mid H_0 \text{ false}) = \beta \text{ probability for type II error power} = 1-\beta$

power analysis & sample size calculation

What is the power of a test

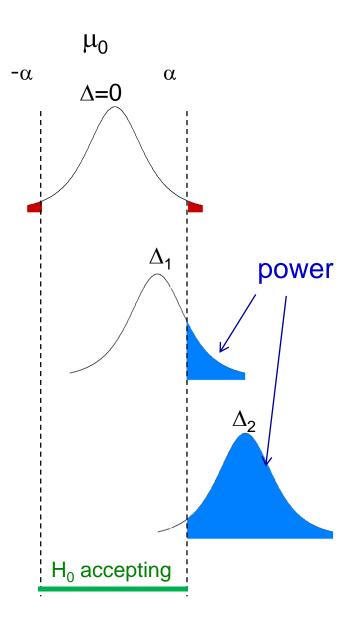

The power $(1-\beta)$, of a test is the probability to reject H_0 , if H_A is true.

The power is given by the blue area.

The larger the difference Δ between H₀ and reality is, the larger gets the power. However, "reality" is not known -> it is hard to estimate the power.

For a given difference Δ between H₀ and reality the power gets bigger if the width of the distribution of the Test-Statistic, e.g. mean, gets smaller which can be achieved by increasing the sample size.

Since the reality can not be changed, in praxis the only way to increase the power is to increase the sample size.

Zurich University of Applied Sciences

Sample size calculation

Situation:

Your group has developed a new drug for sleeping time elongation.

The new drug is only interesting if its sleeping time elongation surpasses the one from the «golden standard» by at leas 1h (relevant effect).

From a pilot study we know the standard deviation of the sleeping time in individual patients is: sd=1 (1h).

Given your drug surpasses the old drug by a mean sleeping time extension of 1h - how big should the sample size be chosen, so that you have a power of 80% and simultaneously an α =5% that your test rejects the H₀ and proves the superiority of the new drug?

Simulation with n=5,10,20

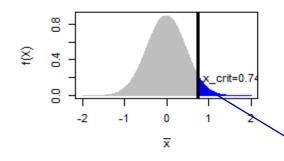

X: Sleep elongation compared the golden standard drug

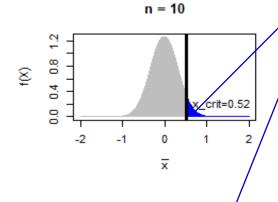

$$H_0$$
: $E(X)_0 = \mu_{\Delta 0} = 0$

Distribution of \overline{X} under H_0

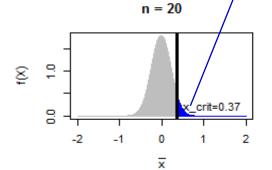

With a sample of size 5 we would reject H_0 , if $\bar{X} > 0.74$

$$\alpha = 5\%$$
 is fixed

With a sample of size 10 we would reject H_0 , if

$$\bar{X} > 0.52$$

With a sample of size 20 we would reject H_0 , if $\bar{X} > 0.37$

Simulation with n=5,10,20

X: Sleep elongation compared the golden standard drug

 $H_0: E(X)_0 = \mu_{\Lambda 0} = 0$

 H_A : $\mu_{\Delta}=1$

Results

One-sample t test power calculation

```
n = 7.727622
delta = 1
sd = 1
sig.level = 0.05
power = 0.8
alternative = one.sided
```

How to plan the size of a study?

- Choose the test you want to use in your analysis
- Determine/Estimate the variation of the observations
- \triangleright fix significance level α (the accepted risk for a type-1-error, typically 5%)
- > Fix relevant effect size (the minimal effect which is still relevant)
- Fix the power which gives the probability to detect an relevant effect (typically 80%)
 - Choose 1-β

Perform a sample-size calculation to derive the needed sample size at which the required power is given.

Good webpage for sample size calculations – menu based, but shows corresponding R-code: http://powerandsamplesize.com/Calculators/

Multiple testing: Rhine Paradox

- The parapsychologist **Joseph Rhine** hypothesized in the 1950's that some people had *Extra-Sensory Perception* (*ESP*).
- He tested for ESP by an experiment where people were asked to guess the color of 10 hidden cards:

red or blue.

■ He discovered that almost 1 in 1000 had ESP – they were able to get all 10 right. Surprised???

$$P(10 \text{ correct answers } | \text{ just guessing}) = \frac{1}{2} \cdot \frac{1}{2} = \left(\frac{1}{2}\right)^{10} = \frac{1}{2^{10}} = \frac{1}{1024}$$

No, 1 in 1024 is what we would expect to get by chance if everybody is just guessing

Multiple testing: Rhine Paradox

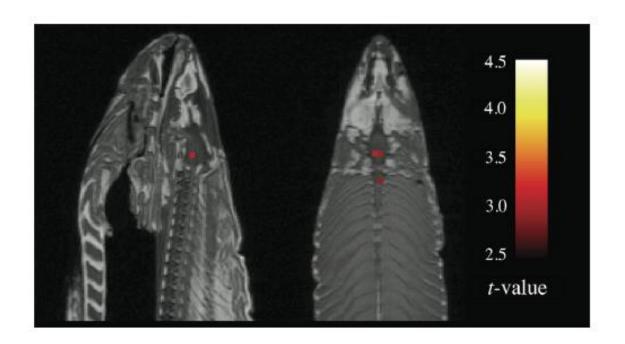

- He told these people they had ESP and called them in for another test of the same type.
- He discovered that all of them had lost their ESP.
- What did he conclude???

Multiple testing: Rhine Paradox

He concluded that you shouldn't tell people that they have ESP, because it causes them to loose it.

fMRI revealed brain response to trans-species emotional stimuli in a dead salmon

A dead salmon was repeatedly confronted with 2 different human emotional stimuli.

Out of 8064 brain voxels in 16 voxels a significant different activity (p≤0.001!) was observed

This study received 2012 the IG nobel price (for *ignoble*, improbable research).

The probability to get by chance a significant test result

The risk to get in **one test** an false positive result (that is $p < \alpha$ under H0) is only

$$P(reject \ H_0 \mid H_0 \ true) = \alpha$$

$$P(accept \ H_0 \mid H_0 \ true) = 1-\alpha$$

Assume n independent test's (with n independent samples) where the null-hypothesis H₀ is always valid (no effect nowhere)

– the probability draw always the right test decision is:

$$P(accept \ n-times \ H_0 \mid H_0 \ true) = (1-\alpha)^n$$

– the probability of coming up with at least 1 false positive effect is:

$$P(\geq 1 \text{ rejecting } H_0 \mid H_0 \text{ true}) = 1 - (1 - \alpha)^n$$

the probability of making at least 1 type one error at n trials, when $\alpha = 0.01\%$

| n | 50 | 100 | 200 | 400 | 800 |
|---------|-----|-----|-----|-----|------|
| P(>1FP) | 39% | 63% | 87% | 98% | 100% |

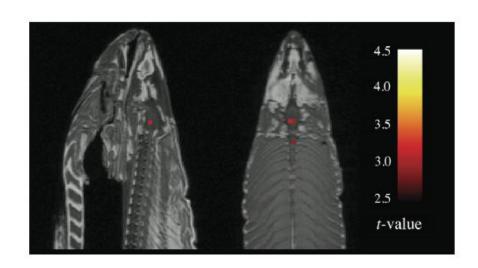

Bonferroni correction for multiple testing and its effect on the dead salmons reaction

Bonferroni: when performing n independentl tests, conduct each test at significance level $\frac{\alpha}{n}$!

When applying Bonferronis rule, we only have a risk of α , to come up with ≥ 1 false positive effects (that is a significant test result although H₀ is true).

No brain region of the dead salmon showed a significant reaction to smiling people after Bonferroni correction.

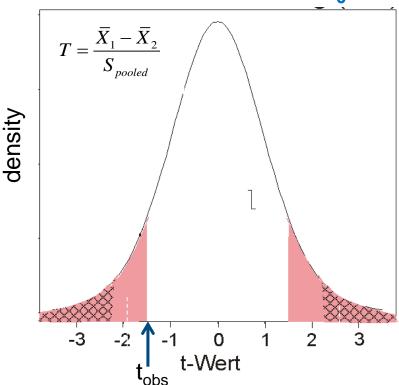

The p-value is uniformly distrubuted under H_0

The p-value corresponds to the probability to get an at least such extreme result as the observed result assuming that the Null-Hypothesis is valid

-> the p-value corresponds to the area in the extreme tails

$$p = Prob(|t| > |t_{obs}| | H_0 true)$$

$$= Prob(|p| \le |p_{obs}| | H_0 true)$$

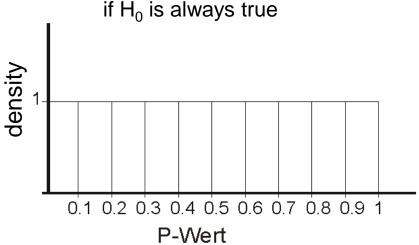

Given H_0 is true in all tests:

p=0.1: 10% of all tests get a p-value≤0.1 if H₀ is always true

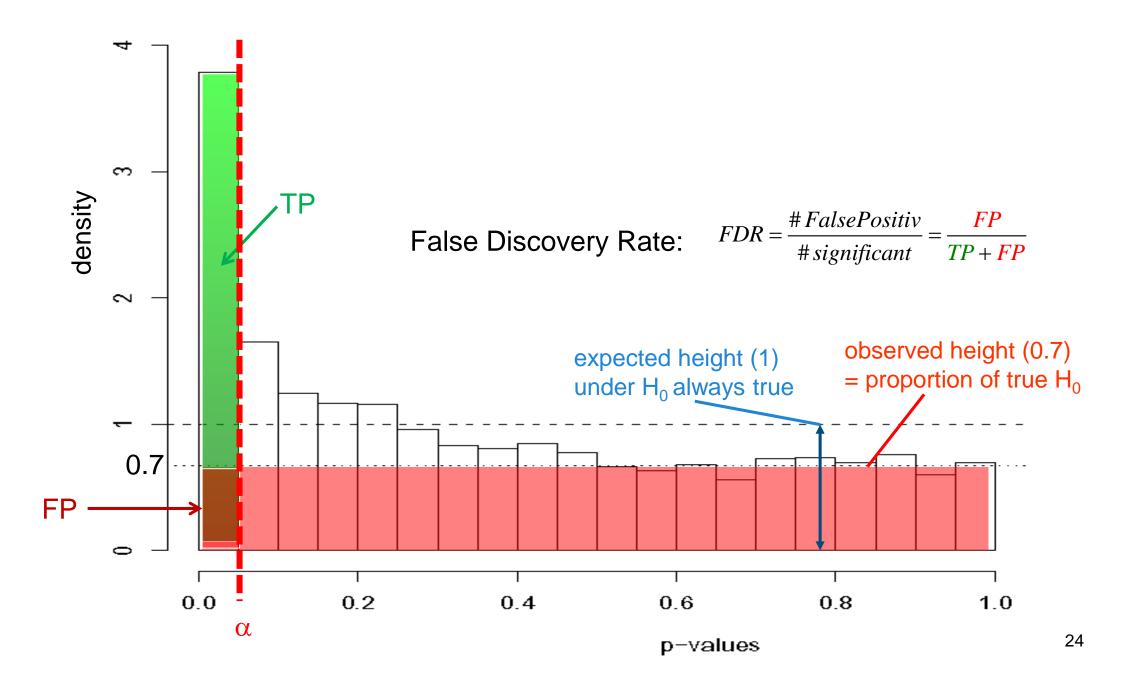

p=0.2: 20% of all tests get a p-value≤0.2 if H₀ is always true

p-Wert Histogramm

if H₀ is always true

How to estimate the ratio p_0 of truly null voxels? How to estimate the false discovery rate?

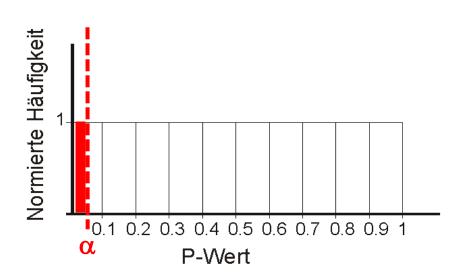

Judging a p-value histogram

The p-value histogram helps to judge the results from many *independent* tests

Flat is Bad!

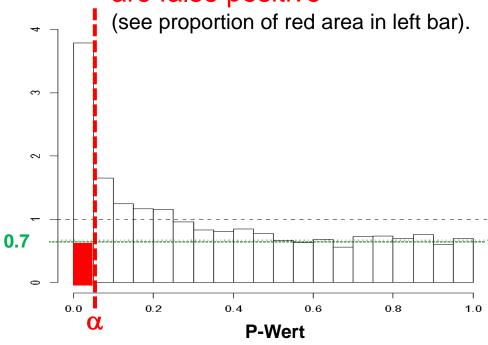

For all tests n independent H_0 is true ~ 100% of all significant findings are false positive.

(see proportion of red area in left bar).

The peak we seak!

For 70% of all tests H_0 is true. Only ~20% of all significant findings are false positive

Take home message Multiple Testing

It is tempting, but not o.k. to forget about all non-significant tests and just publish the significant effects.

You need to take account for the multiple testing

- by p-value correction such as Bonferroni correction or
- using other measures like FDR or
- confirm the "found effect" in a new control experiment.
